MycoApply® – development under drought through mycorrhizal fungi   

- TO REACH WHERE ROOTS CANNOT!

 NEW  MycoApply EndoPrime SC – the new LIQUID formulation from the MycoApply range is now available on the Bulgarian market!

Rate 15 ml/da (quantity of seed sown per decare of area).

MycoApply® EndoMax contains propagating material from four strains of mycorrhizal fungi which colonize the rhizosphere of plants in a symbiotic manner. The mycorrhiza develops rapidly to enormous dimensions,

increasing many times the suction capacity of the root hairs. Owing to this symbiosis, the mycorrhiza forms hyphae through which the plant receives multiple times more water and nutrients, depending on its current needs, regardless of environmental conditions.

MycoApply® is applied by seed treatment prior to sowing, in-furrow at sowing, or by treatment of planting material.

 Increase of root mass:

- The mycorrhizal fungus quickly associates with the root;

- Improves the activity of the conducting system;
- Increases many times the surface area of the roots.

## Efficient nutrition:

- Mycorrhizal fungi absorb and transport nutrients directly to the roots;
- They produce specific enzymes that convert nutrients into an available form: phosphorus, nitrogen, micronutrients.

## Improvement of water regime:

- Mycorrhizal hyphae reach, absorb and transport to the plant even hardly accessible water;
- The fungus forms special structures in the root where water is stored;
- Tolerance to high temperatures, drought, freezing, unsuitable pH or excessive soil salinity is increased.

MycoApply® EndoMax is permitted for use in organic farming in accordance with EU Regulation 834/2007.

The product is compatible with the most commonly used fungicides on the market.
